

# Generics

## Lecture 10

# A Simple Component

- Client-side view: Pencil

```
public interface Pencil {
    String toString();
    void setColor(Colors newColor);
    void sharpen(int remove);
}
```
- Implementer's view: LeadedPencil

```
public class LeadedPencil implements Pencil {
    private static final int STD_LENGTH = 10;
    private Colors color;
    private int length;
    . . . etc . . .
}
```
- See code listings for full documentation

# Pencils

# Background

- Methods are parameterized by the *values* of their formal arguments

```
void enableLaunch (boolean go) { ... }
```

  - In a sense, there are 2 enableLaunch()'s:
    - one where go begins with value true
    - one where go begins with value false
  - Could define enableLaunchT(), enableLaunchF()

```
boolean isEven (int i) { ... }
```
  - In a sense, there are 4,294,967,296 versions of isEven() (half return true, half return false)
  - Could define isEven0(), isEven1(), isEven2(), ...

```
void println (String s) { ... }
```
  - In a sense, there are ?? versions of println()

# Motivation: Using Components

- Consider a box that holds a pencil
  - See BoxOfPencil.java
  - Box contains at most one pencil
  - Methods: size, contains, insert, removeAny
- Aside: Notice "coding to the interface"
  - Method signatures contain **interface** types

```
boolean contains(Pencil target)
void insert(Pencil item)
Pencil removeAny()
```
  - Specifications also contain this type
- Recall: **Declared** vs **Dynamic** type
  - The **dynamic** type of these arguments and return values will be a reference to an instance of a class that *implements* Pencil (eg LeadedPencil)

# Box of Pencils

## Using a Different Component

- Now consider a box that holds a string
  - See BoxOfString.java
- (Aside: Is it coded to the interface?)
- These two class definitions differ *only* in:
  - The argument type of contains()
  - The argument type of insert()
  - The return type of removeAny()
  - The types mentioned in specifications
- All the rest is identical!
- BoxOfPencil and BoxOfString are like two instantiations of a generic class definition
  - Parameterized by *type* (not value)

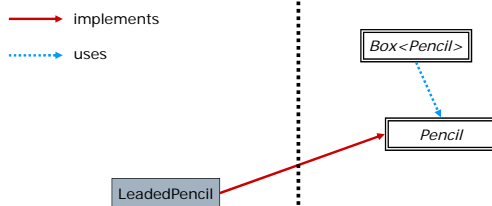

## Example: Generic Box Interface

- Declaration
 

```
interface Box<T> { . . . }
```
- In body of interface declaration, T can now be used as a type
 

```
boolean contains(T target)
void insert(T item)
T removeAny()
```
- See Box.java
- Vocabulary:
  - T is called a *naked type*
  - Box (ie without < >'s) is called a *raw type*

## Box of Pencils

## Example: Generic Implementation

- Declaration
 

```
class PlasticBox<T> implements Box<T> {
    . . .
    PlasticBox() { . . . }
}
```
- In body of class definition, T can now be used as a type
  - In fields
 

```
private T value
```
  - In methods
 

```
public void insert ( T item)
```
- See PlasticBox.java
  - Note: Name of constructor in class definition is PlasticBox(), not PlasticBox<T>()

## Box of Pencils

## Example: Client Use of Generic

- To use generic type: classname<type>
- Usual rules of coding to the interface apply
 

```
Box<Pencil> bp = new PlasticBox<Pencil>();
bp.insert(new LedgedPencil());
Pencil p = bp.remove();

// the following are all errors...
String s = bp.remove();
LedgedPencil p2 = bp.remove();
Box<Pencil> bp2 = new PlasticBox<String>();
Box<Pencil> bp3 = new Box<Pencil>();
```

## Example: Comparable Interface

- Some classes have natural orderings
  - eg `Integer(3) < Integer(14)`
- `java.lang.Comparable`

```
public interface Comparable<T> {
    int compareTo(T o)
}
```

  - Returns negative integer, 0, or positive integer if this object is `<`, `=`, or `>` argument `o`
- Typical use

```
if (p1.compareTo(p2) < 0) // p1 < p2
if (p1.compareTo(p2) == 0) // p1 == p2
if (p1.compareTo(p2) > 0) // p1 > p2
```

## Good Practice: Total Ordering

- `compareTo` should induce a total ordering on its type parameter
  - Reflexive  
`x.compareTo(x) == 0`
  - Transitive  
`x.compareTo(y) < 0 && y.compareTo(z) < 0`  
`==> x.compareTo(z) < 0`
  - Antisymmetric  
`x.compareTo(y) <= 0 && y.compareTo(x) <= 0`  
`==> x.equals(y)`
  - Total
    - Any two instances of `T` can be compared

## Implementing Comparable

- Simple case for typical use

```
public class LeadPencil implements
    Pencil, Comparable<LeadPencil> {
    public int compareTo(LeadPencil o) { . . . }
}
```
- Or even better (coding to the interface!)

```
public class LeadPencil implements
    Pencil, Comparable<Pencil> {
    public int compareTo(Pencil o) { . . . }
}
```
- Or even better (but we'll talk about extends later)

```
public interface Pencil
    extends Comparable<Pencil> { . . . }
public class LeadPencil implements Pencil {
    public int compareTo(Pencil o) { . . . }
}
```

## Example: Lists

- Array size fixed by instantiation with `new`

```
Integer[] A = new Integer[145];
```
- What if you need the array to grow?
  - Allocate new (larger) array
  - Copy old values into new
- Better approach: `java.util.List<T>`
  - Generic interface
  - Holds a (ordered) list of `Ts`
  - Can be accessed by index like an array
  - But also has a dynamically changeable size
- Implementations: `ArrayList`, `LinkedList`, `Vector`
  - `ArrayList` more efficient, need `Vector` for threads

## Using List (and ArrayList)

```
import java.util.List;
import java.util.ArrayList;

List<String> list = new ArrayList<String>();
list.add("Hello");
list.add("there");
list.add(0, "Sam");
System.out.println(list.get(1)); // "Hello"

for (String str : list) {
    System.out.println(str);
} //prints "SamHellothere"
```

## Methods

- Array-like
  - `set` / `get` for index-based access
- Adding items
  - `add(T)` / `add(int,T)`
  - Causes the List to grow
- Removing items
  - `remove(int)` / `removeRange(int,int)`
- Memory management
  - `isEmpty` / `size`

## Type Erasure

- Note: `PlasticBox<Pencil>` and `PlasticBox<String>` are *not* two separate classes
  - They are two generic type *invocations* of *one* class, `PlasticBox`

```
Box<Pencil> b1 = new PlasticBox<Pencil>();
Box<String> b2 = new PlasticBox<String>();
assert b1.getClass() == b2.getClass(); //passes
```
- Think of `<Pencil>` as constructor information, so the compiler can do appropriate casting and type checking
- At run-time, no generic type information remains in `PlasticBox` objects
  - The type parameter, `T`, has been "erased"
  - Left with one class: `PlasticBox<?>` (pronounced "plastic box of unknown")

## Box of Pencils

## Consequences of Type Erasure

- All type-instances share the same static members

```
static int nextID; //shared by all Box<?>
```
- Static members can not refer to naked type

```
private static T value; //compile error
```
- New instances and arrays of naked type can not be created

```
T value = new T(); //compile error
T[] myArray = new T[50]; //compile error
```
- Casts ignore parameter type information

```
Box<String> x = (Box<String>) b; //unchecked
Box<?> y = (Box<?>) b; //ok
```

## Summary

- Genericity through type parameters
  - Declaration of generic interfaces/classes
  - Use of generic interfaces/classes
- Comparable interface
  - Total ordering, strongly typed thanks to generics
- List (and ArrayList)
  - Like arrays, but better!
