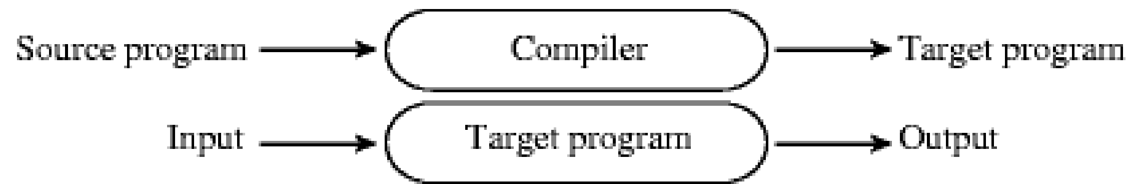
# Introduction

Chapter 1, Sections 1.1, 1.2, 1.5

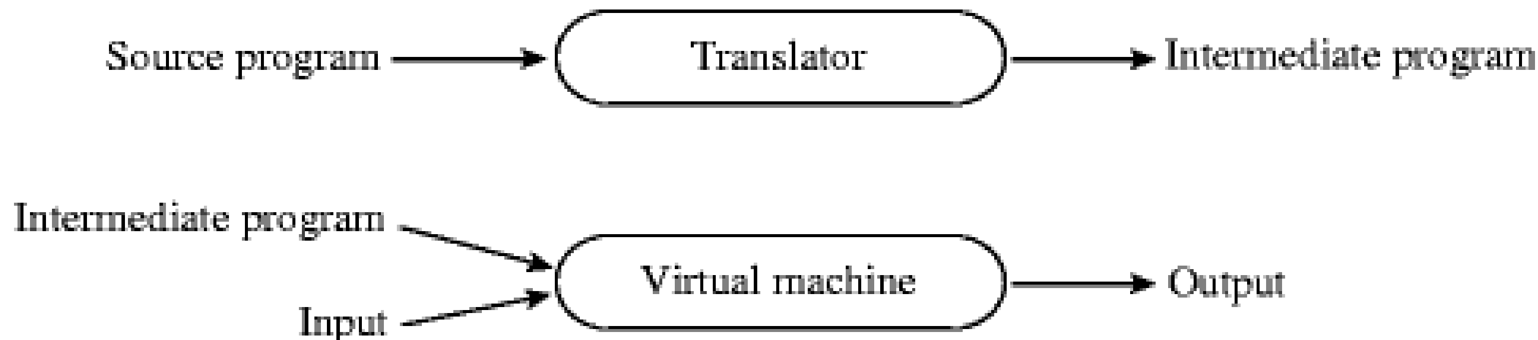
# Implementation Methods

- Compilation (C,C++,Fortran)



- Interpretation (Lisp)

- Hybrid (Java with bytecode, C# with CIL)



# The Entire Toolchain (1/2)

- Preprocessor: source to source translation
  - E.g. GNU C/C++ macro preprocessor **cpp**
    - Inlines **#include**, evaluates **#ifdef**, expands **#define**
    - Produces valid C or C++ source code
- Compiler: source to assembly code
  - E.g. GNU C/C++/… compiler **gcc**
  - Produces assembly language for the target processor
  - Assembly is easier to generate/debug than object code
- Assembler: assembly to relocatable object code
  - E.g. GNU assembler **as**
  - Translates mnemonics (e.g. ADD) to opcodes; resolves symbolic names for memory locations

# The Entire Toolchain (2/2)

- Linker: relocatable object code from several modules (including libraries) to single executable program
  - E.g. GNU linker **ld**
  - Resolves inter-module symbol references; relocates the code (recomputes addresses)
- Example: **gcc** from Unix command line
  - Driver program that invokes the entire toolchain
  - **gcc -E test.c**: preprocessor (output: C code)
  - **gcc -S test.c**: preprocessor+compiler (output: assembly)
  - **gcc -c test.c**: preprocessor+compiler+assembler (output: object code for this compilation unit)

# Inside the Compiler: Front End

- Lexical analyzer (aka scanner)
  - Converts ASCII or Unicode to a stream of tokens
- Syntax analyzer (aka parser)
  - Creates a parse tree from the token stream
- Semantic analyzer
  - Type checking and conversions; other semantic checks
- Generator of intermediate code
  - A parse tree is too high-level for code generation & optimization
  - Create lower-level **intermediate representation** (IR): e.g. three-address code

# Inside the Compiler: Middle Part

- Analysis of intermediate code
  - Additional IRs: control-flow graph (CFG), static single-assignment form (SSA), def-use graph, etc.
  - Control-flow analysis, dataflow analysis, pointer analysis, side-effect analysis, polyhedral analysis, …
- Machine-independent optimization of intermediate code: e.g. better three-address code
  - Copy propagation, dead code elimination, code motion, constant propagation, redundancy elimination, parallelization, data locality optimizations, …
- Currently, this is where most of compiler research is focused

# Inside the Compiler: Back End

- Code generator: from intermediate code to assembly code
  - Instruction selection, register allocation, storage allocation, instruction ordering, …
- Machine-dependent code optimizations
  - Elimination of redundant loads and stores, elimination of unreachable code, flow-of-control optimizations, use of machine idioms (e.g. specialized instructions)
- A symbol table maintains information about names, types, and scopes
  - Used by all phases of the compiler

# The Bigger Picture: Compiler Technology

- Very strong connections with language design and with computer architecture
  - E.g., compiler technology had direct impact on the success of C, C++, Java, and C#
  - E.g., Intel has its own compiler
  - E.g., how are we going to take advantage of multi-core?
- Software engineering tools
  - E.g., IDEs have many code analyses and transformations
  - E.g., static verification tools – heavy use of compiler analyses (beginning to have real-world impact)
  - E.g., automated debugging tools (static & dynamic)
  - E.g., test coverage tools & test generation tools
